(57) **ABSTRACT**

A system is configured to receive vehicle state input, and in response to the vehicle state input, select an operational mode for PWM switching of electronics in a power conversion circuit of a hybrid electric vehicle electric drive system (EDS). Vehicle state input can pertain to EDS state, engine state, and the presence of alternative noise sources, such as audio equipment, climate control equipment, and lowered windows. Various operational modes can include a noise reduction mode in which EDS noise is reduced, a loss reduction mode in which EDS losses are reduced, and a default mode, which can be designed to maximize fuel efficiency. A system can be configured to provide a PWM implementation strategy based on operational mode selection. By way of example, a PWM implementation strategy can comprise random PWM, continuous PWM, discontinuous PWM and fixed frequency PWM.

ADAPTIVE E-DRIVE OPERATION FOR ELECTRIFIED VEHICLE

CROSS-REFERENCE TO RELATED APPLICATIONS

This continuation application claims priority from parent U.S. application Ser. No. 12/686,355 filed on Jan. 12, 2010, which is incorporated herein in its entirety by reference.

BACKGROUND OF INVENTION

1. Field of Invention

The present invention relates to electric drive systems. In particular, the invention pertains to pulse width modulation (PWM) strategies employed at an electric drive system.

2. Background Art

Electric machines, in particular electric or hybrid electric vehicles, may employ electrical energy for propulsion via an electric drive system. An electric drive system can encompass a number of components, typically including at least a power circuit and a motor. In this arrangement, the power circuit can controllably transfer power from a power source to the motor to drive a load. Power circuits for electric drive systems designed for electric or hybrid electric vehicles often include inverters for providing three-phase voltage waves from a dc voltage source. Typically an inverter is composed of a plurality of electronic switches that are controllably turned off and on in various combinations to provide desired inverter output voltages.

It is common practice to use pulse width modulation (PWM) techniques to turn the switches on and off. The rate at which the switches are turned on and off is typically determined by motor speed or torque requirements as well as fuel efficiency considerations. Unfortunately, in many cases, switching the various electronic devices on and off at a particular frequency can generate noise audible to the vehicle driver, as well as his passengers. The noise can be distracting and irritating, and is often the subject of consumer complaints.

Various attempts have been made to reduce or eliminate irritating PWM switching noise at an electric vehicle. For example, PWM switching can be performed at a higher frequency, such as 10 kHz, which is outside the human audible range. However, this solution has its disadvantages. While the higher switching frequency no longer generates noise heard by the operator, it induces power losses in the system that can reduce fuel economy, a long-standing priority for hybrid vehicles, and increase power circuit costs.

SUMMARY OF INVENTION

An example system includes a pulse width modulation (PWM) frequency adaptation mechanism (PFAM) configured to receive vehicle state input, and in response to the vehicle state input, select a PWM operational mode to be implemented at a vehicle electric drive system. The vehicle state input can pertain to additional sources of noise at a vehicle that can mask noise produced by an electric drive system at the vehicle. Possible noise sources include auxiliary systems such as an audio system, a climate control system, lowered windows, an engine, etc. In addition to auxiliary equipment, vehicle state input can also include input regarding engine and electric drive state. A system can further include an apparatus coupled to the PFAM and configured to implement the selected PWM operational mode. By way of example, operational modes can include a

2

noise reduction mode, a loss reduction mode, and a default mode. For example, when noise that can mask the sounds of an electric drive system is present, a default mode can be implemented, while in the absence of alternative noise sources, a noise reduction mode can be implemented. A PFAM can be configured to provide a PWM implementation strategy based on the selected operational mode. By way of example, a PWM implementation strategy can include continuous PWM, discontinuous PWM, random PWM or fixed frequency PWM. In an example embodiment, a PFAM can be configured to receive user input in addition to vehicle state input, and an operational mode can be selected based on both vehicle state input and operator preference input.

The invention departs from the conventional practice of using motor speed torque requirements to select a PWM switching frequency that characterizes electric drive operation. Instead, the invention dynamically adapts electric drive operation by using various vehicle inputs to select an operational mode directed to achieve an objective such as to reduce noise, reduce loss, or optimize fuel usage. A system can further include an apparatus configured to implement the provided PWM strategy, such as a power conversion circuit configured to provide an output voltage using electronic devices that are switched on or off by pulse width modulation implemented in accordance with the PFAM operational mode and PWM strategy.

In an example embodiment, a PFAM can be embodied as a software module embedded at a microprocessor or other digital processing device at a vehicle. For example, a system can include a digital processor and a computer readable medium operatively coupled to the digital processor, having stored thereon logic for sequences of instructions for the digital processor. The sequence of instructions, when executed by the digital processor cause the processor to select a PWM operational mode based on vehicle state input.

An example method can include receiving vehicle state input, and selecting a PWM operational mode based on the received vehicle state input. For example, a method can comprise receiving vehicle motion input, receiving engine state input, receiving ventilation system state input, receiving audio system state input, receiving vehicle body state input, and determining an operational mode in response to the received input. A method can further include receiving user input and selecting an operational mode based on vehicle state input and user input. A method can comprise selecting a noise reduction mode when alternative sources of noise are absent, and selecting a default mode when alternative noise sources are present to mask the noise produced by an electric drive system. A method can include implementing a loss reduction mode when a vehicle state input indicates that an electric drive system is heavily loaded.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic of a vehicle equipped with a PWM Frequency Adaptation Mechanism (PFAM).

FIG. 2 is a block diagram of an example vehicle control system.

FIG. 3A shows a block diagram of an example embodiment.

FIG. 3B depicts a block diagram of an example embodiment.

FIG. 4 shows a flow diagram of an example method of the invention.

FIG. 5 depicts a block diagram of an example apparatus.

FIG. 6 depicts a flow diagram of an example method.
FIG. 7 shows a flow diagram of an example method.

DETAILED DESCRIPTION OF EXAMPLE EMBODIMENTS

Example embodiments of the invention are presented herein; however, the invention may be embodied in a variety of alternative forms, as will be apparent to those skilled in the art. To facilitate understanding of the invention, and provide a basis for the claims, various figures are included in the description. The figures are not drawn to scale and related elements may be omitted so as to emphasize the novel features of the invention. Structural and functional details depicted in the figures are provided for the purpose of teaching the practice of the invention to those skilled in the art and are not to be interpreted as limitations. For example, control modules for various systems can be variously arranged and/or combined, and are not to be considered limited to the example configurations presented herein.

FIG. 1 illustrates a schematic of an example vehicle 100. The vehicle 100 may be of any suitable type, such as an electric or hybrid electric vehicle. In at least one embodiment, the vehicle 100 may include a first wheel set 112, a second wheel set 114, an engine 116, an HEV transaxle 118, an electric drive system (EDS) 120, a power transfer unit 130, a differential 140, and a vehicle control system (VCS) 150.

The EDS 120 may be configured to provide torque to the first and/or second wheel sets 112, 114. For example, the EDS 120 may include a high voltage battery (HVB) 122 and a power electronics converter (PEC) 121 coupled to one or more Permanent Magnet Synchronous Machines (PMSM) 126. The PMSM 126 can be coupled to the power transfer unit 130 or HEV Transaxle 118, which in turn can be coupled to the differential 140 to control the wheel set 114. It is contemplated that the PMSM 126 can function as a motor, converting electrical energy to kinetic energy, or as a generator, converting kinetic energy to electrical energy.

The power transfer unit 130 may be selectively coupled to at least one PMSM 126. The power transfer unit 130 may be of any suitable type, such as a multi-gear “step ratio” transmission, continuously variable transmission, or an electronic converterless transmission as is known by those skilled in the art.

The power transfer unit 130 may be adapted to drive one or more vehicle wheels. In the embodiment shown in FIG. 1, the power transfer unit 130 is connected to a differential 140 in any suitable manner, such as with a driveshaft or other mechanical device.

In an example embodiment, the PEC 121 includes an inverter system control (ISC) 123 comprising hardware, including inverter circuitry, configured to provide power to the PMSM 126. An ISC controller 124 can be coupled to the ISC 123. The ISC controller 124 can be a microprocessor-based device configured to control operation of the ISC 123, and comprise hardware, software, firmware or some combination thereof. In an example embodiment, currents and voltages of the ISC 123 can be controlled by controllably switching ISC circuit elements using pulse width modulation.

The ISC controller 124 may be electrically coupled to the Vehicle Control System (VCS) 150 which is configured to monitor and/or control various aspects of the vehicle 100. The VCS 150 can comprise a VCS controller communicatively coupled to one or more control modules for one or more various systems installed at a vehicle, and/or to sensors

associated with various vehicle systems, and/or to various vehicle components or sensors. FIG. 2 provides an example embodiment 200 of a VCS. The VCS 200 includes a VCS controller in the form of a VCS control module (VCSM) 202, coupled to an engine control module (ECM) 204 for providing engine control and monitoring engine state, a climate control module (CCM) 204 for controlling vehicle interior temperature and ventilation system state, an audio system control module (ASCM) 206 for controlling and/or monitoring audio system operation, and a body control module (BCM) 210 for controlling and/or monitoring aspects of the vehicle body, such as, but not limited to window operation and state. The VCSM 202 can also be communicatively coupled to one or more sensors, such as vehicle speed sensor 212.

In an example embodiment, the VCSM 202 can be in the form of a microprocessor or microcontroller configured to communicate with the various control modules depicted in FIG. 2, as well as other control modules or sensors not shown. The group of control modules depicted in FIG. 2 is not exhaustive, but rather is focused on the components most pertinent for teaching the invention. For example, a VCS can also include a transaxle control module for controlling torque provided to vehicle traction wheels, high voltage battery control module for controlling operation of a high voltage battery, a traction battery control module for monitoring environmental attributes such as temperature, and controlling one or more power sources, a powertrain control module, and other modules associated with various other vehicle systems. Further, it is contemplated that one or more systems, by way of example but not limitation, a vehicle audio system, may not be controlled by a specific module or controller, in which case a VCSM or VCS controller may receive system state input via a sensor or direct connection with a system component. It is noted that functions associated with the control modules and/or sensors depicted in FIG. 2 can be variably combined and/or performed at other vehicle modules or components.

As shown in the example system 100, a PWM Frequency Adjustment Mechanism (PFAM) 125 can be coupled to the ISC controller 124 and the VCS 150. The PFAM 125 can be configured to receive vehicle state input obtained by the VCS 150, and determine at least one PWM parameter in response to the received input. In an example embodiment, the PFAM 125 can provide the at least one PWM parameter to the ISC controller 124, so that the ISC 123 can operate under the PFAM 125-designated PWM parameters. The PFAM 125 can comprise hardware, software, firmware, or some combination thereof, and can be embodied as a stand alone unit, or as a module incorporated or integrated within an existing vehicular component, such as a microprocessor device.

FIG. 3A depicts an example embodiment 300 that includes a PFAM 304 installed at an ISC controller 302. In an example embodiment, the PFAM 304 is in the form of a software module installed and executable at the ISC controller 302. The ISC controller 302 is configured to control operation of the ISC 306. A user input means 308 is coupled to the PFAM 304 and configured to receive operator preferences. For example, some vehicle operators may prefer a noise reduction mode in which designated PWM frequency and strategy reduces PWM switching noise. Other operators may prefer a default operational mode in which PWM parameters are selected without consideration of PWM noise. In an example embodiment, the user input means 308 can be embodied as a button or switch on a vehicle dashboard, preferably easily accessible by the vehicle driver, that

5

can be depressed by a user to indicate that noise reduction is desired. In an example embodiment, the user input means **308** is configured to receive user preference input and provide it to the PFAM **304**.

In an example embodiment, a system can include a PFAM comprising an ISC PFAM portion and a VCS PFAM portion. Referring to FIG. 3B, a system **320** can include an ISC **322** coupled to an ISC controller **324**. An ISC PFAM portion in the form of an IPFAM module **326** can be installed at the ISC controller **324** and be executable thereon. The system **320** can include a VCS **330** having a VCS controller **332**, with a VCS PFAM (VPFAM) module **334** installed and executable thereon. A user input means **328** can be configured to provide user input to the VPFAM module **334**.

In an example embodiment the VPFAM **334** can be embodied as a software module and be configured to receive input regarding a variety of vehicle system and apparatus states via the VCS controller **332**. For example, the VCS controller **332** can be configured to receive vehicle speed information from the vehicle speed sensor **212** and provide it to the VPFAM **334**. The VPFAM **334** can be configured to provide vehicle state input for the IPFAM **326**, for example via the communicative coupling of the VCS controller **332** and the ISC controller **324**. Thus, the VPFAM **334** and IPFAM **326** can cooperate to determine at least one parameter of the PWM practiced at the ISC **322**.

FIG. 4 depicts a flow diagram of an example method **400**. At block **402** vehicle state input can be received at a PFAM. Referring to FIG. 5, an example PFAM **500** can receive vehicle state inputs **504-512** and provide an output **520**. In an exemplary embodiment, the various inputs **504-512** are related to potential noise sources that can be heard by a vehicle occupant. In at least one example, input to the PFAM **502** can include input **504** pertaining to vehicle motion, input **506** pertaining to vehicle engine state, input **508** pertaining to vehicle climate control system state, input **510** pertaining to vehicle audio system state, input **512** pertaining to vehicle window state, and input **514** pertaining to EDS state. In an example embodiment, a VCS provides the inputs **504-512** to the PFAM **502**, while input **514** can be received from a sensor within the EDS **120**. Typically, a VCS can obtain the vehicle state data expressed in the inputs **504-512** from the various vehicle systems to which it is communicatively coupled, without requiring additional sensors or hardware.

The vehicle motion input **504** can comprise information characterizing the speed at which the vehicle is moving. For example, the VSC **150** can provide speed information from the speed sensor **212** to the PFAM **502**. At the PFAM **502** vehicle speed may be characterized categorically as low speed or high speed, by other general categories, or by quantitative terms such as miles or kilometers per hour. At high speeds, engine noise and road noise typically increase and can be louder than the PWM related noise, shielding an operator from the sound of the PWM switching. However at low speeds, engine and road noise are typically lower, causing the PWM related noise to be more noticeable by an occupant, particularly a driver, since an ISC is typically located on the driver's side of a vehicle. In an example embodiment, vehicle motion input comprises vehicle shift input which can indicate whether a vehicle is in a drive mode. When a vehicle is in a drive mode, a noise reduction mode can be selected, while when the vehicle is not in a drive mode, a default mode may be selected.

The engine status input **506** can comprise information pertaining to a vehicle engine mode. An engine can operate in several different modes. In an example embodiment,

6

when an engine is an OFF mode, a vehicle can be driven by an electric motor, necessitating PWM switching of inverter elements that can produce noise that a user may want to avoid. Furthermore, because the engine is in an OFF mode, it is not producing noise, so cannot mask the PWM switching noise. Thus, when an engine is in an OFF mode, a noise reduction mode can be selected. When a vehicle engine is in a cranking mode, engine-generated noise is typically high, and may mask PWM switching noise. Accordingly, a nominal or default PWM mode may be selected. When an engine is in an acceleration or deceleration mode, a noise-reduction mode is generally preferred.

Climate control system status input **508** can comprise information characterizing the operation of the vehicle heating/air conditioning system(s), another potential source of noise that may shield a driver from hearing PWM-related noise. In an example embodiment, climate control system status input **508** comprises data characterizing whether the vehicle air conditioner is turned on or is turned off. In a further example embodiment, the input **508** can comprise data characterizing climate control system fan speed, since a fan can operate to both heat and cool the car. By way of example, but not limitation, fan speed can be expressed in general categories or by specific speeds. Other ways to characterize operation or state of the climate control system will occur to those skilled in the art.

The audio system status input **510** can comprise information pertaining to the vehicle audio system, for example whether a source is providing an audio signal to a speaker. A vehicle audio system can include various audio/visual equipment such as a radio, compact disc player, mp3 player, video player, and the like which can provide audio signals to one or more speakers mounted in the vehicle. The audio projected by the speakers, if sufficiently loud, can hide the noise produced by PWM switching operations. As an example, audio system input can include current operational status of a vehicle radio.

In an example embodiment, audio system state input can comprise a volume setting for the speakers of the audio system, which can be used with various components of a vehicle's audio/visual system. Typically a single volume control, such as the volume control knob of a radio, can control speaker volume for a set of one or more speakers. However, when this is not the case, for example when a built-in video player has a separate volume control, or when rear seat passengers have a separate volume control, audio state input **308** can comprise more than one volume setting. In addition to a volume setting, audio system input **510** can include whether an audio or audio/visual player is actually providing an audio signal. For example, a CD player may be turned on and a volume control knob turned up, but there may be no CD present, so the CD player would not be producing sound.

A lowered window on a vehicle can also be considered a source of noise for those riding in the automobile. In addition to generating its own "road noise", an open window can expose an occupant to various sounds and noises outside the vehicle. Window status input **512** includes information pertaining to whether one or more vehicle windows is lowered; i.e. whether at least one window is open. In an example embodiment, window status input **512** can include the degree to which a window is open and/or identify the open window. For example, a small vent window open in the rear of a van may cause less driver distracting noise than a driver's window that is completely lowered.

In an example embodiment, EDS state input **514** can comprise information that indicates whether an EDS is fully

loaded. By way of example, but not limitation, input **514** can comprise temperature data from a sensor positioned at the EDS, for example within the ISO **123** or at the PMSM **126**. A high temperature reading can indicate that the EDS **120** is fully loaded, in which case power requirements and/or losses can be considered in selection of a PWM parameter.

Using the inputs **504-514**, the PFAM **502** can determine a PWM parameter at block **404**. A PWM parameter can be any attribute that characterizes or quantifies PWM performance. For example, a PWM parameter can comprise a PWM switching frequency, a PWM strategy, or both. By way of example, but not limitation, a PWM strategy can comprise a continuous, non-continuous, or random strategy. In the past, PWM frequency has been selected on the basis of motor state or torque requirement. The present invention provides systems and methods for designating a PWM frequency based on vehicle state information. In an example embodiment, a PWM frequency can be selected that reduces noise while optimizing ISO and vehicle performance. For example, based on vehicle state input that indicate that a set of particular conditions are in effect, a PWM frequency of 7.5 kHz-10.0 kHz can be selected over a default switching frequency of 1.25 kHz-5.0 kHz. In an example embodiment, a PWM strategy can be designated that optimizes performance, whether a high or low PWM switching frequency is specified.

The invention provides a method and system in which vehicle state information can be used to determine whether PWM is performed in a noise-reduction mode or in a default mode. In an example embodiment, when a noise reduction mode is selected, a PFAM provides one or more PWM parameters that can reduce PWM switching noise heard by a driver. By way of example, but not limitation, when a default mode is selected, pulse width modulation is performed without consideration of PWM noise effects. For example, PWM parameters can be specified on the basis of fuel economy.

FIG. 6 depicts a flow diagram of an example method **600**. At block **602** a PFAM can receive user input. For example, the PFAM **502** can receive user preference input **516**. Referring to FIGS. 3A and 5, user input **516** can be received via user input means **308** and provided to the PFAM **304**. In an example embodiment, the user input means **308** is in the form of a button or switch, or other hardware mechanism that can be manipulated by a driver to indicate a desire for PWM noise reduction. As a further example, user input can be programmed, eliminating the need for a hardware input means, and user preference can be stored in software, either at the PFAM **304**, or at another software module in communication with PFAM **304**. For example, a user preference can be programmed in the VCS controller **332** or at a dashboard information center. In an example embodiment, the user preference input **516** comprises an operational mode preference of a driver; for example, whether a noise reduction mode or a default mode is preferred. Some drivers may pay little or no regard to PWM-related noise, and may actually prefer to hear it. Other drivers may find the PWM noise very irritating.

At block **604**, vehicle state input can be received. For example, as discussed above for block **402** of method **400**, input such as that shown in FIG. 5, including vehicle motion input, engine status input, climate control system status input, audio system status input, vehicle body input, and E-drive status input can be received.

At block **606**, a PFAM can designate a PWM operational mode based on user preference and vehicle state inputs. For example, the PFAM **304** can perform an algorithm using the

user preference and vehicle state inputs to determine whether pulse width modulation at an ISO should be performed in a noise reduction mode or in a default mode. In an example embodiment, if a user prefers a default mode, a default mode is selected at the PFAM **304**.

A noise-reduction mode and default mode can be variably defined. In at least one example, a default mode can be characterized by a default switching frequency and/or default PWM strategy, and a noise-reduction mode can be defined as one in which the PWM switching frequency and/or strategy are different from those of the default mode. As a further example, a default mode can be one in which a PWM switching frequency of 5.0 kHz or less is specified by a PFAM, while a noise-reduction mode can be one in which a PWM switching frequency greater than 7.5 kHz is designated. Alternatively, in a default mode a PWM switching frequency within the audible band can be employed, while in a noise-reduction mode a PWM switching frequency outside the audible band can be employed. As a further example, a default mode can include a first set of PWM frequencies and strategies, while a noise-reduction mode can include a different set of PWM frequencies and strategies. Other ways of distinguishing a default mode from a noise-reduction mode will occur to those skilled in the art. By way of example, but not limitation, when a default mode is not preferred by a user or selected by a PFAM, a PWM parameter can be selected that reduces noise or reduces power losses.

At block **608**, at least one PWM parameter is specified in accordance with the selected operational mode. For example, if, based on the received inputs **504-514**, a noise reduction mode is designated, the output **330** can comprise a PWM parameter that can reduce the noise generated during PWM switching. For example, the output **330** can comprise a high PWM switching frequency which is less audible than a lower default switching frequency. Likewise, the output **330** can comprise a PWM strategy, such as random frequency hopping about a specified frequency (whether high or low) that can reduce the noise perceived by an operator. In an example embodiment, the PWM parameter can be provided to an ISO controller that controls ISO operation. For example, the PFAM **212** can designate a PWM strategy and provide it to the ISO controller **210** so that the ISO **216** can implement the designated PWM strategy.

FIGS. 7A and 7B show an example method **700**. At block **702**, an electric drive run mode is entered. At decision block **704** a determination is made as to whether a user prefers a default mode. In an example embodiment, a user can select a preferred operational mode via user input means **328** which can provide the user preference to the IPFAM **326**. By way of example, but not limitation, active selection of a default mode and/or failure of a user to designate a preferred mode other than a default mode, results in selection of a default mode in which a default PWM parameter is selected at block **726**. For example, the IPFAM **326** output can comprise a predetermined default PWM strategy. In an example embodiment, the IPFAM **326** can provide the default PWM strategy to the ISC controller **324** so that the default strategy can be implemented at the ISC **322**.

If a default mode is not selected, for example a user indicates a preference for a noise-reduction mode, the method **700** continues with decision blocks pertaining to the state of various vehicle systems or components. Preferably, vehicle state input comprises status information for vehicle components other than a vehicle motor. In an example embodiment, when vehicle state information indicates the

presence of noise from another source, a default PWM parameter is selected. However, if the user selects a noise-reduction mode, and vehicle state input indicates an absence of other noise, a noise-reduction PWM parameter, rather than a default PWM parameter can be selected.

For example, at decision block **706** a determination is made as to whether a vehicle window is open. As an example, from the VCS controller **310** the PFAM **304** can receive ventilation state input **508** which can include data regarding the state of the vehicle windows. If at least one window is open, the PFAM **304** can designate a default PWM parameter as output at block **726**. If no window is open, the example method **700** can proceed to decision block **708** in which a determination is made as to whether the vehicle air conditioner is turned on. For example, the PFAM **125** can receive ventilation system input **508** which can be in the form of information conveying whether the air conditioner is turned on. Because an operating air conditioner can produce fan noise that can mask PWM switching noise, a determination that the air conditioner is on can lead to block **730** at which a default PWM parameter is specified. Pulse width modulation characterized by the default PWM parameter can be performed at the ISC **123**.

If the air conditioner is not on, the method **700** can proceed to block **710** where a determination can be made as to whether the vehicle radio is on. For example, audio system input **510**, which can be obtained by the VCSM **202** and provided to the PFAM **304**, can comprise information regarding whether a vehicle radio is turned on. If the radio is turned on, the example method **700** can proceed to block **726** at which a default PWM parameter is selected.

If the radio is not turned on, the method **700** can continue to decision block **712** at which a determination is made as to whether the vehicle is in a drive mode. In an example embodiment, this determination is made based on vehicle shift input provided to a PFAM; for example, vehicle motion input **504** can comprise vehicle shift input. If the vehicle is not in drive mode, the method **700** can proceed to block **726** at which a default PWM parameter is specified.

If the vehicle is in drive mode, the method can continue to a decision block **714**, at which a determination is made as to whether the vehicle is accelerating or decelerating. The noise due to PWM switching can be more pronounced during periods of acceleration or deceleration; therefore it is generally desirable to select a noise reduction mode during these periods. Accordingly, the method **700** can continue to block **716**, at which a noise reduction PWM parameter is selected. By way of example, a noise reduction PWM parameter can comprise a high PWM switching frequency. Also by example, a noise reduction PWM parameter can comprise a PWM strategy performed using a high PWM switching frequency. A high frequency can be variably defined. For example, it can be any frequency higher than the frequency used for the default frequency at block **726**. It can also be defined as a frequency greater than a predetermined threshold, or a frequency within a predetermined frequency range. Preferably a high PWM frequency is higher than the band of frequencies audible to the human ear. In an example embodiment, a high frequency can be a frequency higher than 7.5 kHz. In an example embodiment, a PFAM includes a look-up table of low and high frequencies from which a PWM switching frequency can be selected. A PWM strategy using the designated high frequency can then be performed at the ISO **123**. As an example, a random PWM strategy using a high frequency can be practiced.

If the vehicle is moving at a constant speed, i.e. neither accelerating or decelerating, the method can continue to block **718** at which a determination is made as to whether the vehicle is moving at a low speed. Vehicle motion input **504** can comprise vehicle speed information that can be received from a vehicle speed sensor, for example vehicle speed sensor **212**. By way of example, but not limitation, a high speed can be defined as a speed greater than a predetermined threshold. For example, a speed greater than 40 mph can be considered a high speed. At a high speed, the engine typically generates sufficient noise to mask the sound of PWM switching, so the method **700** can continue to block **726** when the vehicle is moving at a high speed. Alternatively, when a vehicle is moving at a low speed, the method **700** can continue to decision block **720** at which a determination is made as to whether the electric drive is heavily loaded. One indication that the electric drive is heavily loaded is that temperature inside an ISO and/or at a PMSM becomes high. For example, an ISO temperature around 110° C. can indicate that the electric drive is heavily loaded. In an example embodiment, the ISC controller **124** can monitor the temperature provided by a sensor within the ISC power stage and/or motor stator windings, and provide EDS state input **514** to the PFAM **502**. By way of further example, the PFAM **502** can directly receive input **514** from a sensor within an EDS. When the electric drive is heavily loaded, use of a high PWM frequency could cause the ISC to overheat, therefore a loss-reduction PWM parameter can be selected at block **722**, such as a low PWM frequency and/or a random PWM strategy. Although a lower frequency generally is less effective in reducing noise because a lower frequency may still be within the audible band of an occupant, the noise effects of a low PWM frequency can be mitigated by proper selection of a PWM strategy. For example employing a random frequency-hopping PWM strategy can spread the power spectrum over a range of lower frequencies, and thereby reduce the PWM-generated noise. If the electric drive is not heavily loaded, a noise-reduction PWM parameter, such as a noise reduction PWM frequency, for example a high PWM switching frequency, which provides better noise reduction, can be tolerated by the ISC and therefore can be selected at block **724**.

Whether the designated PWM frequency is high or low, selection of a PWM parameter can include selection of a PWM strategy to be implemented at the ISC **123**. As mentioned previously, a PWM strategy can include, but not be limited to, continuous PWM, non-continuous PWM or random PWM. Random PWM can be implemented by selecting a frequency at random from a look-up table. Alternatively, random PWM can be practiced by frequency hopping about the designated frequency to diffuse the power spectrum.

Example methods for using vehicle state input to designate one or more PWM parameters for pulse width modulation switching operations at an ISC are presented herein. The use of vehicle state input and/or user preference input to determine the characteristics of the pulse width modulation used at an electric drive system of a hybrid vehicle is in contrast to prior art methods that used motor speed and torque requirements as a basis for designating PWM switching frequencies, strategies or other PWM characteristics. Preferably, vehicle state input comprises information pertaining to potential noise sources at a vehicle, and user preference input comprises a user's desire for a noise-reduction mode. The various inputs can be used to select a PWM parameter that can reduce PWM related noise when desired by a user. Furthermore, methods of the invention can

11

include efficiently entering noise-reduction modes under predetermined conditions, and operating in default modes otherwise, thereby reducing the losses incurred at high switching frequencies, unlike prior art systems that consistently employ high switching frequencies regardless of vehicle state or user preference.

Preferred embodiments rely on software to implement the methods, eliminating the need for additional or customized hardware. Flowcharts included herein represent control logic which may be implemented using hardware, software, or combination of hardware and software. The logic may be implemented using any of a number of known programming or processing techniques or strategies and is not limited to the order or sequence illustrated. Various functions may be performed in the sequence illustrated, at substantially the same time, or in a different sequence while accomplishing the features and advantages of the invention. The illustrated functions may be modified or in some cases omitted without departing from the spirit or scope of the present invention.

What is claimed:

1. A system, comprising:

a pulse width modulation (PWM) frequency adaptation mechanism (PFAM) configured to receive vehicle state input during a run mode of an electric drive system (EDS) at said vehicle, said vehicle state input comprising input pertaining to current status of said vehicle or a component of said vehicle other than an electric motor of said EDS, and in response to said vehicle state input, designate one of a plurality of PWM operational modes to be implemented at said vehicle while said EDS is in said run mode, said PFAM configured to determine, based on said vehicle state input, a presence or an absence of alternate audible noise (AAN) at said vehicle during said run mode, said AAN comprising other than said EDS audible noise;

an apparatus coupled to said PFAM and configured to implement said PWM operational mode, said apparatus comprising a circuit in which elements are switched on and off by PWM performed in accordance with said designated operational mode; wherein said plurality of operational modes includes a noise reduction mode configured to reduce audible noise of said EDS during said run mode, and a default mode;

wherein said PFAM is configured to designate a default mode in response to a determination that said AAN is present; and

wherein said PFAM is configured to designate one of a plurality of PWM implementation strategies based on said designated operational mode, each said strategy comprising a type of PWM characterized by other than frequency.

2. The system of claim 1, wherein said plurality of strategies includes at least two of continuous PWM, discontinuous PWM, random PWM and fixed frequency PWM.

3. The system of claim 1, wherein said PFAM is configured to receive user preference input regarding said PWM operational mode, and use said user preference input and said vehicle state input to designate said PWM operational mode.

4. The system of claim 1, wherein said PFAM is configured to determine whether said EDS is heavily loaded, and if so, designate a loss reduction mode.

5. The system of claim 1, wherein said PFAM is configured to designate said noise reduction mode in response to a determination of an absence of said AAN.

12

6. The system of claim 1, wherein said vehicle state input comprises engine state input, vehicle motion input, climate control system input, window state input and audio system input.

7. A system, comprising:

at least one digital processor;

a computer-readable medium operatively coupled to said at least one digital processor; having stored thereon logic for sequences of instructions for said digital processor, the sequences of instructions, when executed by said digital processor, cause the processor to receive vehicle state input during a run mode of an electric drive system (EDS) at said vehicle, said vehicle state input comprising input pertaining to current status of said vehicle or of a component of said vehicle other than an electric motor of said EDS, and in response to said vehicle state input, designate one of a plurality of pulse width modulation (PWM) operational modes to be implemented at said vehicle while said EDS is in said run mode;

wherein said sequence of instructions, when executed by said digital processor, cause the processor to determine, based on said vehicle state input, a presence or an absence of audible noise at said vehicle other than said EDS audible noise;

wherein said plurality of operational modes includes a noise reduction mode configured to reduce said audible noise of said EDS, and a default mode;

wherein said sequence of instructions, when executed by said digital processor, cause the processor to designate said noise reduction mode in response to a determination that said audible noise other than said EDS audible noise is absent;

wherein said sequence of instructions, when executed by said digital processor, cause the processor to designate said default mode in response to a determination that said audible noise other than said EDS audible noise is present; and wherein said sequences of instructions cause said processor to designate one of a plurality of PWM implementation strategies based on said designated PWM operational mode, said designated PWM implementation strategy comprising a type of PWM characterized by other than frequency.

8. The system of claim 7, wherein said sequence of instructions, when executed by said digital processor, cause the processor to designate a loss reduction mode as said operational mode when said processor determines that said EDS is heavily loaded.

9. The system of claim 7, wherein said vehicle state input comprises engine state input, vehicle motion input, climate control system input, window state input and audio system input.

10. The system of claim 7 wherein said plurality of strategies includes at least two of continuous PWM, discontinuous PWM, random PWM and fixed frequency PWM.

11. A method comprising:

during a run mode of an electric drive system (EDS) at a vehicle, receiving at a pulse width modulation (PWM) frequency adaptation mechanism (PFAM), vehicle state input related to a current status of a vehicle component other than an electric motor of (EDS) of said vehicle; in response to said vehicle state input, said PFAM designating one of a plurality of PWM operational modes for PWM switching in a circuit configured to provide a voltage to an electric motor at said vehicle during said run mode, said plurality of operational modes comprising a noise reduction mode configured to reduce audible noise of said EDS during said run

13

mode, and a default mode; wherein said PFAM is configured to designate, based on said designated operational mode, one of a plurality of PWM strategies to be implemented during said designated operational mode, each said strategy comprising a type PWM characterized by other than frequency; and wherein said PFAM is configured to determine, based on said vehicle state input, a presence or an absence of alternate audible noise (AAN) at said vehicle during said run mode, said AAN comprising other than said EDS audible noise, and to designate said default mode in response to a determination that said AAN is present.

12. The method of claim 11, wherein said PFAM is configured to designate a loss reduction mode.

13. The method of claim 11, further comprising receiving user input regarding said operational mode preference for a default PWM operational mode.

14. The method of claim 11 wherein said designating a PWM operational mode comprises designating a noise reduction mode in response to said vehicle state input indicating said vehicle speed is changing and determining an absence of alternative noise source at said vehicle.

15. The method of claim 11, wherein said designating a PWM operational mode comprises designating a loss reduction mode in response to said vehicle state input indicating said vehicle is traveling at a low speed, and an electric drive system at said vehicle is heavily loaded.

16. The method of claim 11, wherein said selecting a PWM operational mode comprises selecting a noise reduction mode in response to vehicle state input indicating that said vehicle is traveling at low speed and determining an absence of alternative noise at said vehicle.

17. The method of claim 11, wherein said PWM implementation strategy for a loss reduction mode comprises low frequency random PWM.

18. The method of claim 11, wherein said PWM implementation strategy for a noise reduction mode comprises a random strategy performed at a high frequency.

19. A method for designating a pulse width modulation (PWM) parameter, comprising:

a pulse width modulation (PWM) frequency adaptation mechanism (PFAM) receiving vehicle state input during a run mode of an electric drive system (EDS) at said vehicle, said vehicle state input comprising input pertaining to current status of said vehicle or a component of said vehicle other than an electric motor of said EDS, wherein said PFAM, in response to said vehicle state input, is configured

14

to designate one of a plurality of PWM operational modes to be implemented at said vehicle while said EDS is in said run mode, said plurality of operational modes including a noise reduction mode configured to reduce audible noise of said EDS during said run mode, and a default mode, said PFAM configured to determine, based on said vehicle state input, a presence or an absence of alternate audible noise (AAN) at said vehicle, said AAN being audible noise other than said EDS audible noise, wherein said PFAM is configured to designate a default mode in response to a determination that said alternative audible noise is present said PFAM configured to designate one of a plurality of PWM implementation strategies based on said designated operational mode, each said strategy comprising a type of PWM characterized by other than frequency;

said PFAM determining whether a vehicle window is open, and in response to an open window, selecting a default mode and concluding said method, otherwise continuing with said method;

said PFAM determining whether a vehicle air conditioner is operating, and in response to an operating air conditioner, selecting said default mode and concluding said method, otherwise continuing with said method;

said PFAM determining whether a vehicle radio is turned on, and in response to an on state for said radio, selecting said default mode and concluding said method, otherwise continuing with said method;

said PFAM determining whether a vehicle is in a drive mode, and in response to a vehicle not being in a drive mode, selecting said default mode and concluding said method, otherwise continuing with said method;

said PFAM determining whether said vehicle is accelerating or decelerating, and in response to said vehicle accelerating or decelerating, selecting a noise reduction mode and concluding said method, otherwise continuing with said method;

said PFAM determining whether said vehicle is moving at a low speed, and in response to said vehicle not moving at a low speed, designating said default mode and concluding said method, otherwise proceeding with said method; and

said PFAM determining whether an electric drive system (EDS) of said vehicle is heavily loaded, and in response to said EDS being heavily loaded, selecting a loss reduction mode, and in response to said EDS not being heavily loaded selecting a noise reduction mode.
